Understanding Sheaves in Algebraic Geometry

Before delving into equivariance, it is essential to grasp what sheaves are and why they matter.

What Is a Sheaf?

A sheaf is a mathematical tool that systematically records data assigned to open subsets of a topological space, satisfying certain locality and gluing conditions. Sheaves can encode functions, sections of bundles, or other algebraic structures.

Key properties of sheaves:

- Locality: Data over an open set is determined by its restrictions to smaller open subsets.
- Gluing: Compatible local data can be uniquely combined to form global sections.

Sheaves in Algebraic Geometry

In algebraic geometry, sheaves often take the form of sheaves of rings, modules, or more complex structures like coherent or quasi-coherent sheaves. These sheaves play a central role in defining geometric objects such as schemes, stacks, and their morphisms.

Introducing Equivariance in Sheaves

The concept of equivariance introduces symmetry considerations into the framework of sheaves.

What Is an Equivariant Sheaf?

Given a group (G) acting on a space (X) , an equivariant sheaf $(\mathcal{F})$ on (X) is a sheaf that is compatible with the action of (G) . Formally, this involves a collection of isomorphisms that relate the pullback of $(\mathcal{F})$ along the group action to $(\mathcal{F})$ itself, satisfying coherence conditions.

Intuitive picture:

- Think of a sheaf as a way to assign data to open subsets.
- Equivariance ensures that this data "respects" the symmetry of the space under the group action.
- This compatibility allows for transferring local data via the group action consistently.

Formal Definition of Equivariant Sheaves

Suppose:

- (G) is an algebraic group acting on a scheme (X) .
- $(p: G \times X \rightarrow X)$ is the action map.

An equivariant sheaf $(\mathcal{F})$ on (X) consists of:

- A sheaf $(\mathcal{F})$ on (X) .
- An isomorphism $(\phi: p^*\mathcal{F} \rightarrow \mathrm{pr}_2^*\mathcal{F})$, where $(\mathrm{pr}_2: G \times X \rightarrow X)$ is the projection.

This data must satisfy the cocycle condition, ensuring consistency under the group law.

Categories of Equivariant Sheaves

Understanding the structure of equivariant sheaves involves exploring their categorical properties.

The Equivariant Sheaves Category

- Denoted $(\mathrm{Sh}_G(X))$, this category consists of all (G) -equivariant sheaves on (X) .
- Morphisms are sheaf morphisms that are compatible with the (G) -equivariant structure.

Properties:

- Abelian category if the sheaves are coherent or quasi-coherent.
- Closed under kernels, cokernels, extensions, and tensor products, facilitating homological algebra techniques.

Relation to Non-Equivariant Sheaves

- The forgetful functor $(\mathrm{Sh}_G(X) \rightarrow \mathrm{Sh}(X))$ forgets the equivariant structure.
- The category $(\mathrm{Sh}_G(X))$ can be viewed as a category of sheaves equipped with a (G) -action compatible with the sheaf structure.

Equivariant Sheaves and Geometric Quotients

One of the primary motivations for studying equivariant sheaves is their relationship with quotient spaces.

Quotient Schemes and Stacks

- When a group (G) acts on a scheme (X) , the quotient (X/G) may be constructed as a scheme or, more generally, as an algebraic stack.
- Equivariant sheaves on (X) are closely related to sheaves on the quotient (X/G) .

Equivariant Sheaves as Sheaves on the Quotient

- Under suitable conditions (e.g., free and proper group actions), the category of (G) -equivariant sheaves on (X) is equivalent to the category of sheaves on the quotient (X/G) .
- This equivalence underpins many geometric and cohomological computations in equivariant geometry.

Functors in Equivariant Sheaf Theory

Functors are crucial tools for relating categories of sheaves, especially when considering

equivariance.

Pushforward and Pullback Functors

- Given a (G) -equivariant morphism $(f: X \rightarrow Y)$, there are induced functors:
- $(f_*: \mathrm{Sh}_G(X) \rightarrow \mathrm{Sh}_G(Y))$ (pushforward)
- $(f^*: \mathrm{Sh}_G(Y) \rightarrow \mathrm{Sh}_G(X))$ (pullback)

- These functors preserve equivariant structures under appropriate conditions and are vital in cohomology and derived categories.

Equivariant Derived Functors

- Extending to derived categories, one considers derived functors (Rf_*) and (Lf^*) , which compute sheaf cohomology in an equivariant context.
- Derived categories of equivariant sheaves facilitate advanced techniques like spectral sequences and derived functor calculations.

Adjunctions and Equivalences

- Pushforward and pullback functors often form adjoint pairs, preserving important properties.
- Under certain conditions, these adjunctions induce equivalences of categories, especially when passing to quotients or stacks.

Applications of Equivariant Sheaves and Functors

The theory of equivariant sheaves is not purely abstract; it finds numerous applications across various mathematical disciplines.

Representation Theory

- Equivariant sheaves encode group actions on geometric objects, leading to insights into representations of algebraic groups.
- They provide geometric realizations of representations via sheaf-theoretic methods.

Algebraic Geometry

- Used in the study of moduli spaces, especially in the context of vector bundles, principal bundles, and GIT quotients.
- Facilitate the construction of equivariant cohomology theories, which capture symmetry information.

Mathematical Physics and String Theory

- Equivariant sheaves appear in the study of gauge theories, D-branes, and string compactifications.
- They help in understanding symmetry breaking and dualities.

Derived Algebraic Geometry and Stacks

- The language of stacks, which generalize schemes, relies heavily on equivariant sheaves.
- They serve as the building blocks for sheaves on quotient stacks and derived stacks.

Challenges and Future Directions

While significant progress has been made, several challenges and open problems remain:

- Extending equivariant sheaf theory to derived and higher stacks.
- Understanding equivariant sheaves in non-reductive group actions.
- Developing computational tools for explicit descriptions.
- Applying equivariant techniques in new areas such as enumerative geometry and mathematical physics.

Conclusion

Equivariant sheaves and functors form a rich and versatile framework that connects symmetry, geometry, and algebra. They enable mathematicians to study complex geometric objects endowed with group actions, providing tools for quotient constructions, cohomological computations, and representation-theoretic interpretations. As research advances, the interplay between equivariant sheaves, derived categories, and modern geometric theories continues to deepen, promising new insights and applications across mathematics and physics.

Equivariant Sheaves and Functors: A Comprehensive Exploration

Introduction to Equivariant Sheaves and Functors

In modern algebraic geometry and representation theory, the concepts of equivariant sheaves and equivariant functors serve as foundational tools for understanding symmetries in geometric objects and their associated categories. These notions extend the classical ideas of sheaf theory into contexts where group actions or symmetry groups act on spaces and their associated categories, capturing how structures behave under these symmetries.

The notion of equivariance arises naturally in numerous mathematical settings, including the study of quotient spaces, moduli problems, and representation theory. By incorporating group actions into sheaf-theoretic frameworks, mathematicians can analyze how geometric and algebraic objects transform, classify invariant structures, and explore deep dualities.

This detailed review will delve into the definitions, properties, and applications of equivariant sheaves and functors, providing a comprehensive understanding suitable for both newcomers and seasoned researchers.

Fundamental Concepts and Definitions

Group Actions on Topological Spaces and Schemes

To understand equivariant sheaves, it is essential to first grasp the notion of a group acting on a space:

- Group Action: Given a group (G) and a topological space (X) , a left action of (G) on (X) is a map

$$G \times X \rightarrow X, (g, x) \mapsto g \cdot x,$$

]

satisfying:

- $(e \cdot x = x)$ for all $(x \in X)$, where (e) is the identity element.
- $(g \cdot (h \cdot x) = (gh) \cdot x)$ for all $(g, h \in G)$, $(x \in X)$.

- Schemes with Group Actions: In the algebraic setting, a scheme (X) over a base scheme (S) admits a (G) -action if there is a morphism

$$\begin{aligned} & \\ G \times_S X &\rightarrow X, \end{aligned}$$

satisfying analogous axioms.

This action induces symmetry structures on the geometric object, motivating the study of sheaves that respect this symmetry.

Sheaves and Their Equivariance

- Sheaf: A sheaf $(\mathcal{F})$ on a space (X) assigns to each open subset $(U \subseteq X)$ a set (or module, or algebra, depending on context), satisfying locality and gluing axioms.

- Equivariant Sheaf: An equivariant sheaf with respect to a group (G) acting on (X) is a sheaf $(\mathcal{F})$ equipped with additional data that encodes the compatibility of $(\mathcal{F})$ with the (G) -action.

Formal Definition:

Let (G) be an algebraic group acting on a scheme (X) . An equivariant sheaf $(\mathcal{F})$ (more precisely, a (G) -equivariant sheaf) consists of:

- A sheaf $(\mathcal{F})$ on (X) .
- An isomorphism (called the equivariance structure)

$$\begin{aligned} & \\ \phi: \pi_2^* \mathcal{F} &\rightarrow \mu^* \mathcal{F} \end{aligned}$$

on $(G \times X)$, where:

- $\pi_2: G \times X \rightarrow X$ is the projection,
- $\mu: G \times X \rightarrow X$ is the action map.

This isomorphism must satisfy a cocycle condition ensuring compatibility with group multiplication, making the sheaf "respect" the symmetry.

Properties and Construction of Equivariant Sheaves

Categories of Equivariant Sheaves

- The collection of all G -equivariant sheaves on X forms an abelian category, often denoted $\mathrm{Sh}_G(X)$ or $\mathrm{Coh}_G(X)$ when considering coherent sheaves.

- Key properties:
- Stability under kernels, cokernels, and extensions: The category is closed under these operations.
- Forgetful functor: There exists a natural functor

$$\mathrm{For}:$$

$$\mathrm{Sh}_G(X) \rightarrow \mathrm{Sh}(X),$$

$$\mathrm{For}$$

which "forgets" the equivariance structure, forgetting the group action data.

- Equivariant derived category: Extending to complexes and derived functors yields the equivariant derived category, denoted $D^b_G(X)$, capturing sheaf cohomology with symmetry considerations.

Construction Techniques

- Descent Data: Equivariant sheaves can be viewed as sheaves equipped with descent data relative to the quotient X/G . When the quotient exists as a scheme or algebraic space, equivariant sheaves on X correspond to sheaves on X/G .

- Induction and Restriction Functors:
- Restriction: Given a subgroup $(H \subseteq G)$, a (G) -equivariant sheaf restricts to an (H) -equivariant sheaf.
- Induction: Conversely, one can induce (H) -sheaves to (G) -sheaves via pushforward along the quotient map.

- Equivariant Sheaves via Fibered Categories: These are viewed as sections of a fibered category over the base scheme, equipped with a (G) -action compatible with the fiber structure.

Equivariant Functors and Their Role

Definition and Basic Examples

- Equivariant functors are functors between categories of sheaves (or derived categories) that commute with the group action or preserve the equivariance structure.

- Example:
- The pushforward functor $(f_*: \mathrm{Sh}_G(X) \rightarrow \mathrm{Sh}_G(Y))$ associated to a (G) -equivariant morphism $(f: X \rightarrow Y)$ respects the equivariant structures.
- The pullback functor (f^*) also admits an equivariant version when (f) is (G) -equivariant.

Key Point: Equivariant functors are designed to intertwine the group actions, i.e., they are (G) -equivariant functors, satisfying compatibility conditions:

$($

$$F(g \cdot \mathcal{F}) \cong g \cdot F(\mathcal{F}),$$

$)$

for sheaves $(\mathcal{F})$ and group elements $(g \in G)$.

Adjunctions and Equivariant Functors

- Many classical adjunctions extend naturally to the equivariant setting:
- The pair (f^*, f_*) remains adjoint when considering equivariant sheaves.
- The existence of equivariant derived functors such as (Rf_*) and (Lf^*) depends on the

context.

- Equivariant Fourier-Mukai transforms: These are integral transforms between categories of equivariant sheaves, playing a crucial role in derived equivalences and mirror symmetry.

Functoriality and Monoidal Structures

- Equivariant sheaves often form monoidal categories, with tensor products compatible with group actions.

- Equivariant functors preserve these structures, leading to rich interactions with representation theory and categorical symmetries.

Applications of Equivariant Sheaves and Functors

Quotient Constructions and Geometric Invariant Theory (GIT)

- Equivariant sheaves are pivotal in constructing quotients of algebraic varieties or schemes under group actions.

- They facilitate the passage from sheaves on $(X \backslash)$ with group action to sheaves on the quotient $(X/G \backslash)$, especially when the quotient exists as a scheme or algebraic space.

- GIT uses equivariant sheaves to analyze stability conditions and construct moduli spaces.

Representation Theory and Geometric Langlands

- Equivariant sheaves on flag varieties and moduli stacks encode representations of algebraic groups.

- They serve as geometric realizations of representations, with functors translating between sheaf categories and modules.

- The geometric Langlands program heavily relies on equivariant sheaves, especially perverse sheaves and D-modules with symmetries.

Mirror Symmetry and Derived Equivalences

- Equivariant derived categories appear in mirror symmetry, where symmetry groups act on geometric objects, and their derived categories are related via Fourier-Mukai transforms.
- Equivariant sheaves help classify autoequivalences and symmetries within derived categories.

Homological Mirror Symmetry and Categorification

- Equivariant structures enable the categorification of classical invariants, leading
