extraction steam turbine efficiency calculation

Extraction steam turbine efficiency calculation is a critical aspect of thermal power plant engineering that directly influences the performance, fuel consumption, and economic viability of power generation systems. Understanding how to accurately assess the efficiency of extraction steam turbines enables engineers and operators to optimize operations, reduce emissions, and improve overall plant reliability. This comprehensive guide explores the fundamental concepts, methodologies, and practical considerations involved in calculating the efficiency of extraction steam turbines, ensuring you have a clear and detailed understanding of this vital topic.

Understanding Extraction Steam Turbines

What is an Extraction Steam Turbine?

An extraction steam turbine is a type of steam turbine that allows a portion of the steam to be extracted at various stages for other processes, such as feedwater heating, process heating, or district heating. Unlike condensing turbines, which exhaust steam to a condenser, extraction turbines provide a means to utilize steam more efficiently by recovering energy for additional purposes.

Components of an Extraction Steam Turbine

- High-Pressure (HP) Section: Handles high-temperature, high-pressure steam.
- Intermediate-Pressure (IP) Section: Processes steam at intermediate conditions.
- Extraction Points: Specific stages where steam is diverted for external use.
- Low-Pressure (LP) Section: Final expansion stage before exhaust.

Understanding these components is essential because the efficiency calculation depends on the energy transformations occurring at each stage and the extraction points.

Fundamentals of Turbine Efficiency

Definition of Turbine Efficiency

Turbine efficiency measures how effectively a turbine converts the energy in the steam into mechanical work. It is generally expressed as:

$$\eta_{\text{turbine}} = \frac{\text{Actual work output}}{\text{Isentropic work output}}$$

- Actual work output: The real work produced during operation.
- Isentropic work output: The theoretical maximum work if the expansion were ideal and adiabatic.

Types of Efficiency

- Isentropic Efficiency: Compares actual work to ideal isentropic work.
- Mechanical Efficiency: Accounts for mechanical losses in the turbine.
- Overall Plant Efficiency: Considers the entire cycle, including boiler, turbines, condensers, and auxiliary systems.

The Importance of Efficiency Calculation in Extraction Steam Turbines

Efficient extraction steam turbines significantly impact the overall efficiency of power plants. Accurate calculations allow:

- Optimization of steam extraction points.
- Identification of losses and areas for improvement.

- Proper sizing and design of turbines.
- Better operational strategies for fuel savings.
- Compliance with environmental standards.

Methodology for Calculating Extraction Steam Turbine Efficiency

Step 1: Gather Necessary Data

To perform a comprehensive efficiency calculation, collect the following parameters:

- Steam inlet conditions: Pressure (P_{in}), temperature (T_{in}), and enthalpy (h_{in})
- Extraction conditions: Pressure (P_{ex}), temperature (T_{ex}), and enthalpy (h_{ex})
- Exhaust conditions: Pressure ($P_{exhaust}$), temperature ($T_{exhaust}$), and enthalpy ($h_{exhaust}$)
- Mass flow rates: Total and for extracted steam
- Work output: Measured or calculated from turbine shaft power

Step 2: Calculate Theoretical Isentropic Work

Using steam property data (from steam tables or Mollier diagrams):

[

$$W_s = h_{in} - h_s$$

]

Where:

- (h_s) is the enthalpy at the isentropic expansion to the exhaust pressure.

This provides the maximum possible work if the expansion were perfectly adiabatic and reversible.

Step 3: Determine Actual Work Output

Actual work output (W_a) can be obtained from measurements or rated data, considering mechanical losses.

Step 4: Calculate Efficiency

The basic efficiency formula is:

\[

$$\eta_{\text{turbine}} = \frac{W_{\text{a}}}{W_{\text{s}}} \times 100\%$$

\]

In the case of extraction turbines, efficiency calculations must account for the extraction process.

Specific Efficiency Calculations for Extraction Steam Turbines

Accounting for Extraction Steam

For turbines with extraction points, the efficiency calculation becomes more involved because a portion of the steam energy is diverted. The total work can be viewed as the sum of:

- Work from main expansion: Up to the extraction point.
- Work from the extracted steam: Used for auxiliary processes.

Step 1: Calculate Work before Extraction

Using enthalpy data at inlet and extraction point:

\[

$$W_{\text{main}} = h_{\text{in}} - h_{\text{extraction}}$$

\]

Step 2: Calculate Work of Extracted Steam

From the extraction point to the exhaust:

\[

$$W_{\text{extracted}} = h_{\text{extraction}} - h_{\text{exhaust}}$$

\]

Step 3: Total Actual Work

Total work produced:

\[

$$W_{\text{total}} = W_{\text{main}} + W_{\text{extracted}}$$

\]

Step 4: Theoretical Isentropic Work

Compute the ideal (isentropic) expansion from inlet to exhaust for the main and extraction streams:

\[

$$W_{\text{s,main}} = h_{\text{in}} - h_{\text{s,extraction}}$$

\]

\[

$$W_{\text{s,extracted}} = h_{\text{extraction}} - h_{\text{s,exhaust}}$$

\]

Total ideal work:

\[

$$W_{\text{s,total}} = W_{\text{s,main}} + W_{\text{s,extracted}}$$

\]

Step 5: Calculate Efficiency

\[

$$\eta_{\text{extraction}} = \frac{W_{\text{total}}}{W_{\text{s,total}}} \times 100\%$$

\]

This comprehensive approach ensures the efficiency reflects the actual performance, including the extraction process.

Fundamental Concepts in Turbine Efficiency

Thermal Efficiency

Thermal efficiency of a steam turbine is a measure of how well it converts the input thermal energy into mechanical energy. It is influenced by the inlet conditions, expansion process, and extraction points.

Isentropic Efficiency

A key metric used in turbine efficiency calculations is the isentropic efficiency, which compares actual performance to an idealized, reversible process. It is defined as:

\[

$$\eta_{is} = \frac{\text{Actual work output}}{\text{Work output in an ideal isentropic process}}$$

\]

This parameter accounts for real-world irreversibilities and losses, providing a standardized measure of turbine performance.

Calculating Extraction Steam Turbine Efficiency

Core Components of the Calculation

Efficiency calculation for extraction steam turbines involves analyzing multiple parameters:

- Inlet conditions: pressure, temperature, enthalpy
- Outlet conditions: exhaust pressure, temperature, enthalpy
- Extraction points: pressure, enthalpy, and the amount of steam extracted
- Work output: shaft power produced

The core idea is to compare the actual work produced with the ideal, isentropic work, considering the energy taken away with the extracted steam.

Step-by-Step Calculation Methodology

A typical approach involves the following steps:

- Determine Inlet State:
 - Obtain inlet pressure (P_{in}), temperature (T_{in}), and enthalpy (h_{in})
 - Use steam tables or Mollier diagrams to find h_{in} and entropy (s_{in})
- Identify Extraction Conditions:
 - Record extraction pressure (P_{ext})
 - Determine enthalpy (h_{ext}) at extraction point
- Determine Exhaust (or Condenser) Conditions:
 - For the remaining expansion, find the exhaust pressure (P_{exh}), temperature (T_{exh}), enthalpy (h_{exh}), and entropy (s_{exh})
- Calculate Actual Work Output:
 - The actual work per unit mass is:

\[

$$W_{\text{actual}} = h_{\text{in}} - h_{\text{exh}}$$

\]

- Adjust for the mass flow rate and the amount of steam extracted

- Calculate Theoretical (Isentropic) Work:

- Assume an ideal, isentropic expansion from inlet to exhaust:

\[

$$h_{\text{s}} \text{ at } P_{\text{exh}} \text{ with } s_{\text{in}}$$

\]

- The isentropic enthalpy at the exhaust:

\[

$$h_{\text{s}} = h(P_{\text{exh}}, s_{\text{in}})$$

\]

- The ideal work per unit mass:

\[

$$W_{\text{is}} = h_{\text{in}} - h_{\text{s}}$$

\]

- Compute Efficiency:

- The efficiency is then:

$$\eta_{\text{turbine}} = \frac{W_{\text{actual}}}{W_{\text{is}}} = \frac{h_{\text{in}} - h_{\text{exh}}}{h_{\text{in}} - h_{\text{s}}}$$

- Adjust for Extraction and Internal Losses:
- Incorporate the effect of the extracted steam by considering the energy balance of the extraction process
- Factor in mechanical and aerodynamic losses, often derived from operational data

Advanced Considerations in Efficiency Calculation

Partial vs. Full Extraction

Efficiency calculation can vary depending on whether the turbine is designed for full or partial extraction. Partial extraction involves complex energy accounting, as the energy removed impacts the remaining expansion process.

Multiple Extraction Points

In turbines with multiple extraction points, each stage's extraction alters the energy flow. The efficiency calculation must then include the cumulative effects, summing the energy extracted at various stages.

Impact of Losses and Irreversibilities

Real turbines experience various losses:

- Mechanical losses: bearing friction, blade vibrations
- Aerodynamic losses: blade profile inefficiencies
- Heat losses: conduction, convection
- Leakage and internal flow disturbances

These factors reduce the actual efficiency below the ideal calculations, emphasizing the need for

empirical correction factors or detailed performance curves.
