Question What is the primary function of the respiratory system in anatomy and physiology? The primary function of the respiratory system is to facilitate gas exchange, supplying oxygen to the blood and removing carbon dioxide from the body. How do the different types of muscle tissues differ in structure and function? Skeletal muscles are voluntary and striated, responsible for body movements; cardiac muscles are involuntary, striated, and found in the heart; smooth muscles are involuntary, non-striated, and found in organs like the intestines and blood vessels. What are the main components of the nervous system involved in reflex actions? The main components include the sensory receptors, sensory neurons, the central nervous system (brain and spinal cord), motor neurons, and effectors like muscles or glands. Describe the pathway of blood flow through the heart. Blood flows into the right atrium from the body via the superior and inferior

vena cavae, then to the right ventricle, which pumps it to the lungs via the pulmonary arteries. Oxygenated blood returns from the lungs to the left atrium, then passes into the left ventricle, which pumps it through the aorta to the rest of the body. What is the role of the kidneys in maintaining homeostasis? The kidneys filter blood to remove waste products and excess substances, regulate electrolyte balance, control blood pressure through fluid regulation, and maintain acid-base balance. How do the structures of the small and large intestines differ in function? The small intestine is mainly responsible for digestion and nutrient absorption, with its three parts being the duodenum, jejunum, and ileum. The large intestine primarily absorbs water and electrolytes, forms and stores feces, and houses gut bacteria. What is the significance of the myelin sheath in the nervous system? The myelin sheath insulates nerve fibers, increasing the speed of electrical impulse transmission along neurons, which is essential for rapid communication within the nervous system. Which hormones are involved in regulating blood glucose levels, and how do they work? Insulin decreases blood glucose by facilitating cellular uptake and storage as glycogen, while glucagon increases blood glucose by stimulating glycogen breakdown in the liver.
